Summary: Objective: In the Czech Republic, it is possible, to carry out Medical Termination of Pregnancy (MToP) in the 1st trimester up until the 49th day of secondary amenorrhea. The aim of the study is to analyse the significance of serum/urine human chorionic gonadotropin (hCG) assessment and ultrasound (US) examination in pregnancy diagnosis and MToP follow-up. **Methods:** In 2017–2018, MToP was carried out in a total of 109 women by administering a combination of mifepristone (600 mg orally) and misoprostol (400 mcg orally). Serum/urine (LSUP – low sensitivity urine pregnancy test) hCG assessment and US examination were performed at pregnancy diagnosis and MToP follow-up. **Results:** At pregnancy diagnosis, there was a positive and medium strong correlation between serum hCG and size of the gestational sac – GS ($R = 0.711$; $P < 0.0001$) and crown-rump length of the embryo – CRL ($R = 0.605$; $P < 0.0001$). Gestational age was 42–49 days (average 45.6, median 45 days), the women were 16–44 years of age (average 29.4, median 29 years). In MToP follow-up, serum hCG level was $> 1,000$ IU/L in 13.8% of women (15/109) and a positive LSUP test in 17.4% (20/109). US examination diagnosed ongoing pregnancy in five women and missed abortion in one woman (serum hCG was always $> 1,000$ IU/L and LSUP test was always positive). In 5.5% of women (6/109), a subsequent surgical intervention was carried out including those with ongoing pregnancy ($N = 5$); missed abortion ($N = 1$) was treated by additional misoprostol, where surgical intervention was not necessary. **Conclusion:** At pregnancy diagnosis, there is a positive and medium strong correlation between serum hCG and CRL. In MToP follow-up, a negative LSUP test enables reliable exclusion of ongoing pregnancy and missed abortion. In case of a positive LSUP test, US examination should be performed; however, surgical intervention should not be indicated solely on the basis of uterine cavity dilatation.

Key words: medical termination of pregnancy – 1st trimester – human chorionic gonadotropin – ultrasound

Introduction

Medical Termination of Pregnancy (MToP) in the first trimester was first introduced in 1988 in France, followed by China [1]. Gradually this treatment method spread throughout the world

and is preferred by many women [2]. The World Health Organisation (WHO) has found it to be a safe and effective method to terminate pregnancy [3]. Clients who select the pharmacological method over surgery prefer to

avoid general anaesthesia, in favour of an overall more natural and intimate course of terminating pregnancy than with the surgical method [4–6]. MToP using the combination of mifepristone and misoprostol is available in the Czech

Souhrn: Cíl: V České republice lze ženě uměle ukončit těhotenství farmakologickou metodou (UUT-F) v I. trimestru do 49. dne sekundární amenorey. Cílem studie je analýza významu stanovení lidského choriového gonadotropinu (hCG) v séru/moči a ultrazukového (UZ) vyšetření při diagnostice těhotenství a hodnocení výsledku UUT-F. **Metodika:** V letech 2017 a 2018 bylo na našem pracovišti provedeno UUT-F celkem u 109 žen sekvenčním podáním mifepristonu (600 mg perorálně) a misoprostolu (400 mcg perorálně). Stanovení hCG v séru/moči a UZ vyšetření byly provedeny při diagnostice těhotenství i hodnocení výsledku UUT-F. **Výsledky:** Při diagnostice těhotenství byla pozitivní a středně silná korelace mezi hCG v séru a průměrem gestačního váčku v dutině děložní (GS – gestational sac) ($r = 0,711$; $p < 0,0001$) i velikostí zárodka v dutině děložní (CRL – crown-rump length) ($r = 0,605$; $p < 0,0001$). Délka těhotenství byla 42–49 dní amenorey (průměr 45,6; medián 45), ženy byly ve věku 16–44 let (průměr 29,4; medián 29). Při kontrolním vyšetření po UUT-F byla u 13,8 % žen (15/109) hodnota hCG v séru $> 1\ 000$ IU/l a u 17,4 % (20/109) byl pozitivní low sensitivity urine pregnancy test (LSUP test). UZ vyšetření diagnostikovalo „Pokračující těhotenství“ u pěti žen a zamklé těhotenství u jedné ženy (hCG v séru bylo vždy $> 1\ 000$ IU/l a LSUP test byl vždy pozitivní). U 5,5 % žen (6/109) byla provedena následná chirurgická intervence vč. „Pokračujícího těhotenství“ ($n = 5$); u zamklého těhotenství ($n = 1$) byl podán další misoprostol a chirurgickou intervencí nebylo nutné provést. **Závěr:** Při diagnostice těhotenství je pozitivní a středně silná korelace mezi hCG v séru a CRL. Při kontrolním vyšetření po UUT-F umožní negativní LSUP test spolehlivě vyloučit pokračující těhotenství. V případě pozitivního LSUP testu by mělo být provedeno ultrazukové vyšetření, nicméně chirurgická intervence by neměla být indikována pouze na základě rozšíření dutiny děložní.

Klíčová slova: umělé ukončení těhotenství farmakologickou metodou – I. trimestr – lidský choriový gonadotropin – ultrazuk

Republic since 2014 and is being used increasingly [7,8].

Since its introduction in the Czech Republic, MToP has undergone modifications in an effort to simplify the conditions of use. This benefits the client as well as the physician providing the treatment. In the past, the following conditions had to be met – secondary amenorrhea 42–49 days and confirmation of a prosperous intrauterine pregnancy (2–9 mm embryo with present pulsation of the circulatory system). Currently, the lower limit has been eliminated, therefore this method may also be used to terminate very early pregnancies, in which ultrasound (US) is not able to confirm prosperous pregnancy (less than 6 weeks of amenorrhea); however, serum human chorionic gonadotropin (hCG) values may be used [9,10]. The method may also be used for unprosperous pregnancies. Even in such cases, MToP is considered effective and safe [11,12]. The pregnancy must be confirmed by US examination and/or hCG test. Being able to reliably evaluate the success of the method by ruling out continuing pregnancy is crucial [13] and again US examination and/or hCG test is used [14–16]. The objective of our study was to analyse and compare hCG values in serum/urine with ultrasound examination during pregnancy diagnosis and MToP follow-up.

Materials and methods

Prospective cohort study conducted during 2017–2018. The inclusion criteria were as follows: prosperous intrauterine pregnancy, singleton pregnancy, crown-rump length of the embryo – CRL 2–9 mm, secondary amenorrhea 42–49 days (average 45.6; median 45 days), and women 16–44 years of age (average 29.4; median 29 years).

Each pregnancy was diagnosed by transvaginal US examination and hCG blood draw. Initially there were 137 women interested in MToP and participation in the study. In 32 women there was no embryo present on the initial US examination (no prosperous intrauterine pregnancy was detected, which was one of the inclusion criteria). These women were invited for a follow-up examination and subsequently an unprosperous pregnancy was diagnosed in 7 of them, therefore they were excluded from the study. In the remaining 25 women, a prosperous intrauterine pregnancy was confirmed, and they were included into the study. In 10 women, the CRL was more than 9 mm and they were also excluded from the study. In total, MToP was performed in 120 women. Follow-up is lacking in 11 women (MToP was performed but they did not attend the follow-up visits). Therefore, a total of

109 women who met the inclusion criteria, underwent MToP and completed follow-up were included in the study.

MToP was performed by administering oral mifepristone (Mifegyne 200 mcg[®]) 600 mcg and oral misoprostol (Misopreg-nol 400 mcg[®]) 400 mcg in a 36–48-h interval. Combining the two drugs is more effective than monotherapy [17].

MToP follow-up took place 2–5 weeks later, all women underwent US examination and serum hCG and urine hCG (LSUP test – low sensitivity urine pregnancy) values were determined.

Results

At pregnancy diagnosis, there was a medium strong positive correlation between serum hCG and the gestational sac – GS ($R = 0.711$; $P < 0.0001$) and CRL ($R = 0.605$; $P < 0.0001$). Gestational age was 42–49 days (average 45.6; median 45 days), and the women were 16–44 years of age (average 29.4; median 29 years). In MToP follow-up, serum hCG $> 1,000$ IU/L was present in 13.8% of women (15/109) with a positive LSUP test in 17.4% (20/109). US examination diagnosed ongoing pregnancy in five women and a missed abortion in one woman (serum hCG was always $> 1,000$ IU/L and LSUP test always positive). In 5.5% of the women (6/109),

Fig. 1. Pregnancy diagnosis – correlation between serum hCG and US finding in the uterine cavity.

Intrauterine singleton pregnancy, the embryo with blood circulation pulsation was still not present (N = 32). In 21.9% of women (7/32), a subsequent unprosperous pregnancy was diagnosed (red). The strength of association between hCG and GS was measured using Spearman correlation coefficient. There was a medium strong positive correlation: $R = 0.600$; $P = 0.0003$. The slope of regression line showed the trend, there is a regression equation and coefficient of determination, denoted R^2 .

Obr. 1. Diagnostika těhotenství – závislost hCG v séru a ultrazvukového nálezu v dutině děložní.

Nitroděložní jednočetné těhotenství, ještě ale nebyl přítomen zárodek s pulzací krevního oběhu ($n = 32$). U 21,9 žen % (7/32) bylo následně diagnostikováno „neprosperující těhotenství“ (červená). Korelace mezi hCG a GS byla ověřena pomocí Spearmanova korelačního koeficientu. Korelace je pozitivní a středně silná: $r = 0,600$; $p = 0,0003$. Směr závislosti je naznačen regresní přímkou, u které je uvedena regresní rovnice a hodnota koeficientu determinace R^2 .

a subsequent surgical intervention was carried out, including in the women with ongoing pregnancy (N = 5); the case of the missed abortion (N = 1) was treated by additional misoprostol, not surgery.

Pregnancy diagnosis is clearly depicted in Fig. 1–4.

MToP follow-up is clearly depicted in Fig. 5–8.

Discussion

Pregnancy diagnosis

The objective of the work was to confirm a correlation between hCG levels and ultrasound findings at pregnancy diag-

nosis. During the course of pregnancy, hCG levels change significantly. The hCG value is zero in non-pregnant women. In the early phases of pregnancy, hCG values double every 48–72 h and reach a peak at 8–11 weeks of pregnancy and will then gradually decline during the remainder of the pregnancy [18]. In the early stage of pregnancy, hCG increases daily by approximately 50% [19]. There is great individual variability in hCG values. Therefore, it is practically impossible to date a pregnancy based solely on hCG levels and hCG is used primarily to diagnose (confirm) a pregnancy [20].

Fig. 2. Pregnancy diagnosis – correlation between serum hCG and US finding in the uterine cavity.

Intrauterine singleton pregnancy, the embryo with blood circulation pulsation was still not present, only subsequently prosperous (N = 25). The strength of association between hCG and GS was measured using Spearman correlation coefficient. There was a medium strong positive correlation: $R = 0.711$; $P < 0.0001$. The slope of regression line showed the trend, there is a regression equation and coefficient of determination, denoted R^2 .

Obr. 2. Diagnostika těhotenství – závislost hCG v séru a ultrazvukového nálezu v dutině děložní.

Nitroděložní jednočetné těhotenství, ještě ale nebyl přítomen zárodek s pulzací krevního oběhu, jen následně prosperující ($n = 25$). Korelace mezi hCG a GS byla ověřena pomocí Spearmanova korelačního koeficientu. Korelace je pozitivní a středně silná: $r = 0,711$; $p < 0,0001$. Směr závislosti je naznačen regresní přímkou, u které je uvedena regresní rovnice a hodnota koeficientu determinace R^2 .

The value of hCG from which US examination would always be able to identify an intrauterine gestational sac is unknown [21]. Ultrasound examination is used to date a pregnancy [22]. Nonetheless, the results of this work reveal that during pregnancy diagnosis, there is a positive and medium strong correlation between serum hCG levels and US findings (GS and CRL). However, a single value of hCG cannot predict if the pregnancy will be prosperous or unprosperous. Similarly, the value of hCG or CRL at the diagnosis of pregnancy cannot predict the success of MToP.

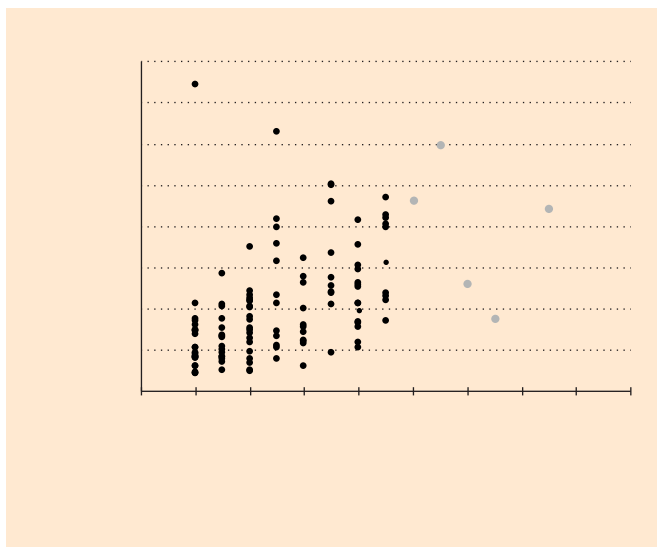

Fig. 3. Pregnancy diagnosis – correlation between serum hCG and US finding in the uterine cavity.

Intrauterine singleton pregnancy, the embryo with blood circulation pulsation was present, CRL ≥ 2 mm (N = 130). In 7.7% of women (10/130), CRL > 9 mm was present and MToP was not carried out (grey). In 9.2% of remaining women (11/120), MToP follow-up was missed. The strength of association between hCG and CRL was measured using Spearman correlation coefficient. There was a medium strong positive correlation: $R = 0.605$; $P < 0.0001$. The slope of regression line showed the trend, there is a regression equation and coefficient of determination, denoted R^2 .

Obr. 3. Diagnostika těhotenství – závislost hCG v séru a ultrazvukového nálezu v dutině děložní.

Nitroděložní jednočetné prosperující těhotenství, přítomen zárodek s pulzací krevního oběhu, CRL ≥ 2 mm (n = 130). U 7,7 % žen (10/130) bylo CRL > 9 mm (šedá) a MToP nebylo provedeno. U 9,2 % ze zbývajících žen (11/120) nebylo provedeno kontrolní vyšetření po MToP (černá) – chybí follow-up. Korelace mezi hCG a CRL byla ověřena pomocí Spearmanova korelačního koeficientu. Korelace je pozitivní a středně silná:

$r = 0,605$; $p < 0,0001$. Směr závislosti je naznačen regresní přímkou, u které je uvedena regresní rovnice a hodnota koeficientu determinace R^2 .

Medical termination of pregnancy may also be used in the very early stages of pregnancy (<6 weeks of amenorrhea), where US cannot yet demonstrate a prosperous pregnancy (embryo with a present pulsation of the circulatory system) and we are guided by serum hCG values. In these cases, MToP is just as effective and safe as in the later weeks [23,24]. The method can also be used in cases of missed abortion. However, the inclusion criteria of this study

were stricter (evidence of a prosperous intrauterine pregnancy), while women with unprosperous pregnancies in the early stages were excluded. Our data reliably reflect the effectiveness of MToP in cases of prosperous pregnancies and our results are therefore more accurate.

The study consisted of oral sequential administration of mifepristone and misoprostol up to 49 days of amenorrhea. It is the only legislatively approved form of administration in the Czech Repub-

lic [9]. Misoprostol may be used on its own [25–27], but appears to be more effective when used in combination with mifepristone [17,28,29].

MToP follow-up

This study confirmed that MToP is a safe and effective method of terminating pregnancy. Failure of this method (ongoing pregnancy) was seen in 4.6% of women. Usually, the failure rate of this method is reported between 1–3% [30].

Fig. 5. MToP follow-up – serum hCG decrease of previous level.

MToP follow-up visit to rule out “Ongoing pregnancy” (N = 104). In one woman (hCG decrease to 2.6%), an “Incomplete abortion” was diagnosed and treated by Surgery (red). In one woman (hCG decrease to 34%), a missed abortion was diagnosed and treated by additional misoprostol (green). In one woman (hCG decrease to 74.9%), an “Incomplete abortion” was diagnosed with expectant management (blue).

Obr. 5. MToP follow-up – pokles hCG v séru (% původní hodnoty).

Kontrolní vyšetření po MToP, vyloučení „Pokračující těhotenství“ (n = 104). U jedné ženy (pokles hCG v séru na 2,6 % původní hodnoty) byl diagnostikován nekompletní potrat a byla provedena chirurgická intervence (červená). U jedné ženy (pokles hCG v séru na 34,0 % původní hodnoty) bylo diagnostikováno zamlklé těhotenství, byl podán další misoprostol a chirurgickou intervencí nebylo nutné provést (zelená). U jedné ženy (pokles hCG v séru na 74,9 % původní hodnoty) byl diagnostikován nekompletní potrat s očekávaným managementem (modrá).

At MToP follow-up, the relation between US examination and serum/urine hCG levels was analysed. There is a significant decrease in hCG levels in the first few days following MtoP [31–33]. This study also reported a significant decrease in hCG levels after successful MToP. However, low levels of hCG may persist 4–6 weeks after complete abortion. Therefore, a routine, high sensitivity urine pregnancy test with a positive result is not suitable for determining the effectiveness of MToP [1].

Establishing the serum hCG level is a very reliable method [15,34], which was also confirmed in this study. All on-

going pregnancies and missed abortions were diagnosed using a cut-off value of 1,000. Establishing the serum hCG level is not influenced by experience of the examiner, as is the case during US examination. A disadvantage is the necessity of a blood draw from the woman. Both the US examination and blood draw require the woman to visit the medical facility. This may lead to a loss in follow-up of some women and possibly non-recognition of an ongoing pregnancy, such as in women with no pregnancy symptoms [35].

In the hands of an experienced physician, US examination is a fast and effective method. If the US examination is performed by an inexperienced examiner,

Fig. 6. MToP follow-up – serum hCG.

MToP follow-up check; excluding “Ongoing pregnancy” and missed abortion, but serum hCG was always > 1,000 IU/L (N = 103). In 8.7% of women (9/103), serum hCG > 1,000 IU/L was present (red). In 13.8% of women (15/109), serum hCG > 1,000 IU/L was present including “Ongoing pregnancy” (N = 5) and missed abortion (N = 1).

Obr. 6. MToP follow-up – hCG v séru.

Kontrolní vyšetření po MToP, vyloučení „Pokračující těhotenství“ a zamlklé těhotenství, u kterých ale bylo hCG v séru vždy > 1 000 IU/l (n = 103). U 8,7 % žen (9/103) byla hodnota hCG v séru > 1 000 IU/l (červená). U 13,8 % žen (15/109) byla hodnota hCG v séru > 1 000 IU/l v „Pokračujícího těhotenství“ (n = 5) a zamlklého těhotenství (n = 1).

who does not have sufficient experience with the MToP method, it can lead to excessive indications for instrumental revision of the uterine cavity. Enlargement of the uterine cavity and the presence of blood coagula may be misinterpreted to be residual tissue. Surgical intervention should be performed on the basis of clinical symptoms, such as heavy or prolonged bleeding, not solely based on ultrasound examination (with the exception of a continuing pregnancy) [14,16]. Only one woman from our set had to undergo surgical intervention after successful MToP due to clinical symptoms, even though the enlargement of the uterine cavity was not significantly greater than in the other women.

The LSUP test is an alternative for follow-up after MToP. The test is comparably successful to ultrasound examina-

Fig. 7. MToP follow-up – serum hCG / LSUP test. MToP follow-up check; excluding “Ongoing pregnancy” and missed abortion, but serum hCG was always >1,000 IU/L and LSUP test always positive (N = 103). In one woman, a false negative LSUP test was present (green). In six women, a false positive LSUP test was present (red). In 17.4% of women (20/109), a positive LSUP test was present including “Ongoing pregnancy” (N = 5) and missed abortion (N = 1).

Obr. 7. MToP follow-up – hCG v séru / LSUP test. Kontrolní vyšetření po MToP, vyloučeny „Pokračující těhotenství“ a zamklé těhotenství, u kterých ale bylo hCG v séru vždy > 1 000 IU/l a LSUP test byl vždy pozitivní (n = 103). U jedné ženy byl LSUP test falešně negativní (zelená). U šesti žen byl LSUP test falešně pozitivní (červená). U 17,4 % žen (20/109) byl LSUP test pozitivní v „Pokračujícího těhotenství“ (n = 5) a zamklého těhotenství (n = 1).

Fig. 8. MToP follow-up – US uterine cavity dilatation. MToP follow-up check; excluding “Ongoing pregnancy” and missed abortion (N = 103). In 1% of women (1/103), a subsequent surgical intervention was carried out (red). In 5.5% of women (6/109), a subsequent surgical intervention was carried out including “Ongoing pregnancy” (N = 5); missed abortion (N = 1) was treated by additional misoprostol, not by surgery. Obr. 8. MToP follow-up – šířka dutiny děložní při ultrazvukovém vyšetření.

Kontrolní vyšetření po MToP, vyloučeny „Pokračující těhotenství“ a zamklé těhotenství (n = 103). U 1,0 % žen (1/103) byla provedena následná chirurgická intervence (červená). U 5,5 % žen (6/109) byla provedena následná chirurgická intervence v „Pokračujícího těhotenství“ (n = 5), u zamklého těhotenství (n = 1) byl podán další misoprostol a chirurgickou intervencí nebylo nutné provést.

tion [36]. In our patient set, the LSUP test diagnosed all ongoing pregnancies as well as missed abortions. The client can perform the test by herself in a home setting and report the result over the phone. In combination with a series of questions regarding bleeding and pregnancy symptoms, it is also a very effective method [37]. For most women this would be the method of choice to monitor the success of MtoP [38,39].

Conclusion

At pregnancy diagnosis, there is a medium strong positive correlation between serum hCG and CRL. In MToP follow-up, a negative LSUP test enables reliable exclusion of ongoing pregnancy and missed abortion; in case of a positive LSUP test, US examination should

be performed; however, surgical intervention should not be indicated solely on the basis of uterine cavity dilatation.

Declarations

Ethics approval and consent to participate

All women in our study had to submit a written request for termination of pregnancy and meet the conditions for the provision of this health service established by the legislation of the Czech Republic. Before the provision of the health service, they signed a detailed informed consent to the provision of the health service, its description and subsequent data collection. During the study, all women at the University Hospital Olomouc, requesting a pharmacological termination of pregnancy, underwent the same procedure,

which was completely in accordance with the latest world knowledge. Our study was not an experiment; it was the provision of an implemented health service and the collection of data from this service. At that time, it was the standard protocol at the Olomouc University Hospital.

The study (research) protocol was approved by the Ethics committee of the Olomouc University Hospital and Faculty of Medicine Palacky University Olomouc.

All methods were carried out in accordance with relevant guidelines and regulations.

Informed consent was obtained from all subjects.

Availability of data and materials

The datasets generated and/or analysed during the current study are not publicly

available, as they are clinical data from the Olomouc University Hospital, but are available from the corresponding author upon reasonable request.

Publication ethics: The Editorial Board declares that the manuscript met the ICMJE uniform requirements for biomedical papers.

Publikační etika: Redakční rada potvrzuje, že rukopis práce splnil ICMJE kritéria pro publikace zasílané do biomedicínských časopisů.

Conflict of interests: The authors declare they have no potential conflicts of interest concerning the drugs, products or services used in the study.

Konflikt zájmů: Autoři deklarují, že v souvislosti s předmětem studie/práce nemají žádný konflikt zájmů.

Dedication: Supported by the Ministry of Health of the Czech Republic – RVO (FNOL, 00098892).

Dedikace: Podpořeno MZ ČR – RVO (FNOL, 00098892).
